Windows Forensics – Part III

Part 1: Non-technical summary:

In this lab, we explored how everyday computer activity can leave behind digital footprints that can be used in an investigation. We focused on the fifth, sixth, and eighth steps within the Windows Forensics methodology: Cache, cookies, and history analysis, Windows file analysis, and event logs analysis. When analyzing the data created by the Windows web browser, we used special tools such as NIRSOFT and Python. Using these tools, we were able to view this stored data and look at a user's internet history, saved cookies, and cached images to see which website was visited and when.

Next, we moved on to analyzing system logs and registry data, which record important events and patterns within the operating system. This information ultimately helps investigators piece together what happened on a machine, including user activity and system changes. We also practiced extracting sensitive system files and analyzed them in a different environment to retrieve account names and encrypted passwords.

Lastly, we used Python to examine the Windows recycle bin. By “undeleting” files and identifying the specific user ID linked to them, we were able to prove exactly who deleted certain data. In the end, this showed how simple tasks like emptying the trash leave behind important evidence that can be used within an investigation to connect actions to a user.

Part 2: Technical summary:

To begin this lab, we concentrated on web browser artifacts using **NIRSOFT** tools. The main job of a web browser is to store valuable forensic information on the host computer. Browsers also store items like caches, browsing history, and cookies. When visiting a website, the web browser stores certain information gathered from the visited site. A computer browsing history contains a list of visited webpages, their titles, the time of visit, etc. Web servers keep track of established sessions with users, such as when the user uses a web browser. The web server creates small packets of information called cookies and stores them on the user's machine.

The first task we completed was downloading and unzipping a list of tool files of Chrome and Mozilla cache, history, and cookies. When trying to download **Chrome Cookies**: https://www.nirsoft.net/utis/chrome_cookies_view.html, I received a message stating it was unable to download because a virus was found. After successfully unzipping the files, I ran **ChromeCacheView.exe**.

ChromeCacheView: C:\Users\vboxuser\AppData\Local\Google\Chrome\User Data\Default\Cache\Cache_Data

This tool had various columns of information from Google Chrome cache, including the filenames, URL, content type, file size, last accessed, the website, cache name, and more.

The next file I ran was **ChromeHistoryView.exe**. This tool lists all the history from Google Chrome. The columns included information like the URL, title, when the site was visited, how often the site was visited, etc.

ChromeHistoryView

Since the Chrome cookies download detected a virus, my Windows virtual machine did not allow me to proceed with the download, and I was unable to perform step 5 for Chrome.

I repeated the same steps above for the Mozilla Firefox browser. I first opened **MozillaCacheView.exe**, then **MozillaHistoryView.exe**, and lastly **MozillaCookiesView.exe**. Each window had the same setup and columns as the Chrome version.

In the second part of this lab, we focused on viewing, monitoring, and analyzing Windows events. If a security incident occurs, investigators are able to analyze the security logs, system logs, and application logs in order to analyze the sequence of events leading up to the crime. I began this process by downloading the **Event Log Explorer**.

After successfully downloading this tool, the window above appeared. I selected **admin events**, and this pulled up a list of tasks on this device.

The third part of this lab was very brief. In this part, we extracted forensic data from computers using **OSForensics**. I downloaded the free version of **OSForensics** first. I then downloaded a small drive image from the Digital Corpora website, created a case, and analyzed the downloaded image.

When I double-clicked the image I downloaded and added to the case, a window opened, revealing the image's hexadecimal values.

The fourth part of this lab covered extracting the **Windows Security Account Manager (SAM)**. The SAM file on the Windows operating system stores users' names and hashed passwords. These files are used when the system is running. I used the following commands within the screenshots below to retrieve the system files. Each command was successful.

```
C:\Windows\system32>reg save hklm\sam c:\work\sam
The operation completed successfully.

C:\Windows\system32>reg save hklm\security c:\work\security
The operation completed successfully.

C:\Windows\system32>reg save hklm\system c:\work\system
The operation completed successfully.
```

I then had to create a shared folder between my hosting operating system and the Linux virtual machine for the next command to work. The command I input into Linux was **sudo samdump2 system sam1** in order to dump the content of the SAM file using the tool samdump2. I received an error initially because I was in the wrong folder. I changed the directory first to **/media/sf_work** and then input the **samdump2** command, which led to a successful output.

```

(kali@kali)-[/media/sf_work]
$ sudo samsdump2 system sam
*disabled* Administrator:500:aad3b435b51404eeaad3b435b51404ee:31d6cfe0d16ae931b73c59d7e0c089c0:::

```

In the fifth part of this lab, we concentrated on handling Windows registry using Python. In order to access registry hives, I inserted the following code in the screenshot below and received the same output that was shown in the lab instructions, listing the registry hives.

```

lab9_part5.py
1  #-*- coding: utf-8 -*-
2
3  Created on Thu Mar 26 16:29:25 2026
4
5  @author: sarah
6  """

```

In the second-to-last part of this lab, we focused on handling Windows recycle bin using Python. The **winshell** module used in this code provides access to Windows shell functions, including the recycling bin, special folders, file operations, shortcuts, and structured storage.

```

import winshell
import re

r = list(winshell.recycle_bin())

for x in r:
    print(x.original_filename(), x.recycle_date(), sep='\t')

f1 = r[0].filename()
y = re.search(r"S.*\d{4}", f1)
print(y.group(0))

path = r'C:\Users\sarah\Documents\test.txt'
with open(path, 'w') as file:
    file.write('This is a test file')

winshell.delete_file(path)

winshell.undelete(path)

```

```

x_not_found_in_recycle_bin: C:
\Users\sarah\Documents\test.txt not found in
the Recycle Bin

```

In this code, we create a test file, delete it, and then undelete it. After running the code above, my device was unable to find the test document within the recycle bin.

The last part of this lab touched on reading browser history, cookies, and cache using Python. Using the code below, we are able to find the path to the Mozilla Firefox files as well as a list of the contained database files.

```

import os

path = r'C:\Users\sarah\AppData\Roaming\Mozilla\Firefox\Profiles\wp9z10of.default-release'

files = os.listdir(path)

for file in files:
    if file.endswith(".sqlite") or file.endswith(".db"):
        print(file)

```

```
In [44]: %runfile 'C:/Users/sarah/OneDrive/Documents/Digital
Forensics/lab9_part6.py' --wdir
bounce-tracking-protection.sqlite
cert9.db
content-prefs.sqlite
cookies.sqlite
domain_to_categories.sqlite
favicons.sqlite
formhistory.sqlite
key4.db
logins.db
permissions.sqlite
places.sqlite
protections.sqlite
storage.sqlite
suggest.sqlite
tabnotes.sqlite
webappsstore.sqlite
```

This output includes the contained database files. In order to find the browsing history within the Firefox browser, we use the code below.

```
import os
import sqlite3

path = r'C:\Users\sarah\AppData\Roaming\Mozilla\Firefox\Profiles\wp9zl0of.default-release'

files = os.listdir(path)

for file in files:
    if file.endswith(".sqlite") or file.endswith(".db"):
        print(file)

history = os.path.join(path, 'places.sqlite')
history_connect = sqlite3.connect(history)
history_cursor = history_connect.cursor()

history_cursor.execute("PRAGMA table_info(moz_places)")
results = history_cursor.fetchall()

statement = 'SELECT url, visit_count FROM moz_places;'
history_cursor.execute(statement)
results = history_cursor.fetchall()
```

```
In [50]: %runfile 'C:/Users/sarah/OneDrive/Documents/Digital
Forensics/lab9_part6_2.py' --wdir
bounce-tracking-protection.sqlite
cert9.db
content-prefs.sqlite
cookies.sqlite
domain_to_categories.sqlite
favicons.sqlite
formhistory.sqlite
key4.db
logins.db
permissions.sqlite
places.sqlite
protections.sqlite
storage.sqlite
suggest.sqlite
tabnotes.sqlite
webappsstore.sqlite
```

This output includes a list of the browsing history files that came from Mozilla Firefox.
